# Transient Simulation of a Diesel Engine as a Tool for Virtual Calibration

## Aspects of transient engine simulation:

- Combustion should be calculated or be given as a table versus engine speed and load
- Combustion with rel. AFR below 1.0 has to be taken into account
- Wall heat losses have to be calculated transiently, taking into account heat capacities of the walls
- Turbocharger modeling

## Summary:

- An application of CPOWER was shown.
- The linked calculation of GT-Power and Simulink models the transient behavior of turbo-charged passenger car diesel engine.
- The integrated simulation of engine and ECU helps to analyze the transient engine behavior more detailed than it was possible up to now.
- This tool helps to pre-optimize control strategies and to design model-based controllers, such as
  - VNT actuation
  - fuel rate dependence on
    - > EGR scavenging and
    - > boost pressure rise
